Birds of Barra Honda National Park

The results of the first year in the bird survey were successful; in total we found 111 species of birds in different places around of Barra Honda hill. To collect this data we used two different methodologies in the survey; counting points in to the forest and points count for species that move over the canopy. In the first methodology we chose five different trails (Pozo Hediondo-Terciopelo, Sendero principal, Laureles-Mirador, Ronda-Mantequilla and Palma Pozo), in those places we marked seven spots which are divided by 250m each. We recorded the counting points over a period of one year. The data was collected by staff members and volunteers.

With point counts for species that move over the canopy, we chose four high places (Mirador Nacaome, Piedra del rey, Frijoleras Santa Ana and Frijoleras Golfo), with open views (picture #xxx). With the other method we did one spot per week, collecting the data of the birds we saw during the census time. By combining the methodologies and different techniques, we achieve more effective results as we obtain the number of species quicker. In the following paragraph we will discuss the results of the survey from the first year.

Point counts for species that move over the canopy

With this technique we obtained a total of 49 species of 29 different groups of birds. In this case, the groups with more numbers of species were Pssitacidae (Parrots), Falconidae (falcons) and Tyrannidae (Flycatchers), the most common species being Black Vulture (41%, n=574), Turkey Vulture (24% n=344) (Vultures) and the Orange-fronted parrot (4,8%, n=67). Using this methodology we managed to see some species that only move through the air and are very difficult to see in to the forest, like the Plumbeos Kite which is a migratory species from North America to Argentina. Through this methodology it becomes possible to see these species which appear only for a short time in Costa Rica.

Points count in to the forest

We did 35 points in total in Barra Honda hill which were each evaluated once per month. The species richness with this method was greater, giving us a total of 82 species from 28 different groups of birds. The Flycatchers, Warblers and Hummingbirds were the groups with more species recorded. The Banded Wren (14, 36%, n=136), Long-tail Manakin (12, 46%, n=118), and Rufous-capped Warbler (12, 46%, n=118) were the more common species documented using this method.

We found 15 migratory species that use the park as a shelter during the winter in North America, however, if we continue evaluating the place we may possibly find even more. Currently, around 200 migratory species have been found in Costa Rica. The data that we are collecting is very important because Guanacaste is the south border of the dry forest in Central America, and the species that are living in this habitat are very difficult to find in other places in Costa Rica.

One of the aims of this survey was to obtain the species that are using the national park as a shelter during the migration time; some of them use Barra Honda for a few days, while others stay until the end of winter in North America. For example, the Broad-winged Hawk stays in Barra Honda from October until April and then migrates back to North America.

According to the investigation conducted, Barra Honda serves as an important habitat, as it provides shelter to 25 migratory species during the migration season, which will hopefully increase over the next few years. By continuing with the investigation, we can obtain more data and demonstrate to communities and schools, through environmental education, the importance of Barra Honda National Park in the protection of our natural resources.

Species data collected with the method of Point counts for species that move over the canopy.
